Formalizing Fermat's Last Theorem

Sep 4, 2026

*"We are sharing the first complete computer-checked proof of Fermat's Last Theorem. Claude worked largely autonomously over 11 days to write the proof in the **Lean programming language**."*

The IMO Grand Challenge (2023)

IMO Grand Challenge

The [International Mathematical Olympiad](#) (IMO) is perhaps the most celebrated mental competition in the world and as such is among the ultimate grand challenges for Artificial Intelligence (AI).

The challenge: build an AI that can win a gold medal in the competition.

Committee

- [Daniel Selsam](#) (OpenAI)
- [Leonardo de Moura](#) (Microsoft Research)
- [Kevin Buzzard](#) (Imperial College London)
- [Reid Barton](#) (University of Pittsburgh)
- [Percy Liang](#) (Stanford University)
- [Sarah Loos](#) (Google AI)
- [Freek Wiedijk](#) (University of Nijmegen)

AlphaProof & the International Math Olympiad (2024)

Score on IMO 2024 problems

Determine all real numbers α such that, for every positive integer n , the integer

$$\lfloor \alpha \rfloor + \lfloor 2\alpha \rfloor + \dots + \lfloor n\alpha \rfloor$$

is a multiple of n . (Note that $\lfloor z \rfloor$ denotes the greatest integer less than or equal to z . For example, $\lfloor -\pi \rfloor = -4$ and $\lfloor 2 \rfloor = \lfloor 2.9 \rfloor = 2$.)

Solution: α is an even integer.

`open scoped BigOperators`

```
theorem imo_2024_p1 :
  { (α : ℝ) | ∀ (n : ℕ), 0 < n → (n : ℤ) | (∑ i in Finset.Icc 1 n, [i * α]) }
= { α : ℝ | ∃ k : ℤ, Even k ∧ α = k } := by
  rw [(Set.Subset.antisymm_iff), (Set.subset_def)], ]
/- We introduce a variable that will be used
   in the second part of the proof (the hard direction) -/

Extensibility and Introspection

*"At Google DeepMind, we used Lean to build AlphaProof, a new reinforcement-learning based system for formal math reasoning. **Lean's extensibility and verification capabilities were key in enabling the development of AlphaProof.**" — Pushmeet Kohli, Vice President, Research Google DeepMind*

Lean 4 is implemented in Lean, allowing for unprecedented extension and introspection by users.

leanprover-community/repl is a simple Lean program for communicating with the Lean compiler via JSON.

AI labs have customized it in many ways, especially around parallelized proof tree search.

stanford-centaur/PyPantograph is the state of the art for open-source Lean REPLs.

Autoformalization (2025)

Auguste Poiroux

Dear all,

We, at Math, Inc., are excited to introduce [Gauss](#), a new autoformalization agent designed to assist mathematicians in their Lean formalization.

Using Gauss, and building over the recent [medium PNT progress](#) by Kontorovich et al., we formalized the **strong Prime Number Theorem** in Lean. Over the course of three weeks, Gauss produced ~25k lines of Lean code and over 1,000 theorems and definitions. To put these numbers in perspective, our previous iteration, three months ago, produced ~3.5k lines of Lean code and 100 theorems and definitions to formalize the [abc conjecture almost always](#).

Our goal is to make Gauss accessible and easy to use. If you are interested, you can register for early access to Gauss [here](#). We are happy to discuss about Gauss and Math, Inc. in the discussion thread.

Vibe Proving (2025)

Forbidden Sidon subsets of perfect difference sets,
featuring a human-assisted proof

Boris Alexeev

ChatGPT*

Lean[†]

Dustin G. Mixon^{‡§}

Abstract

We resolve a \$1000 Erdős prize problem, complete with formal verification generated by a large language model.

In over a dozen papers, beginning in 1976 and spanning two decades, Paul Erdős repeatedly posed one of his “favourite” conjectures: every finite Sidon set can be extended to a finite perfect difference set. We establish that $\{1, 2, 4, 8, 13\}$ is a counterexample to this conjecture.

During the preparation of this paper, we discovered that although this problem was presumed to be open for half a century, Marshall Hall, Jr. published a different counterexample three decades *before* Erdős first posed the problem. With a healthy skepticism of this apparent oversight, and out of an abundance of caution, we used ChatGPT to vibe code a Lean proof of both Hall’s and our counterexamples.

Not Just Mathematics

SymCrypt is Microsoft's core cryptographic library, being rewritten in Rust and verified with Lean and AI.

"We are verifying code faster than we can write it." — Son Ho, Azure Research

lean-zip (Kim Morrison, Lean FRO) is a formally verified and optimized DEFLATE implementation in Lean, implemented entirely by loosely supervised AI.

**Where do we go
from here?**

That Question of Trust

Verification

Check it yourself

- You need Linux or macOS (some paths are too long for Windows), [elan](#) (it installs Lean 4.33.1 from `Lean-toolchain`), and a network connection: Lake fetches Mathlib from GitHub and compiles it from source, since no prebuilt Mathlib matches this toolchain (about 13 minutes at 96 jobs).
- The build needs about 5 GB of memory per parallel job (a few modules need up to 36 GB); about 67 GB of disk under `.lake/`, plus C files (about 220 GB) that can be deleted as the build goes. Ours took 5 h 32 min at 96 jobs, with a peak of 153 GB of memory.
- comparator takes about 15 hours (ours: 14 h 46 min), nearly all of it the kernel replay on one core. **Our peak memory was 230 GB, so allow 300 GB.** Run nanoda after the comparator script, whose tools it reuses. Writing the 37.8 GB export takes about 90 GB of memory for an hour, and the check itself about 40 GB (about 30 minutes at 16 threads). Both scripts are for Linux (bash, git, python3, GNU coreutils; nanoda also needs `patch`, `cargo` and crates.io).

Recapping the Trusted Code Base

In theory, you only have to trust the statement of a proof and the kernel.

In practice, the meaning of statements can be affected by preceding/imported code... and all executed code may potentially influence everything else anyway.

Isolation, in multiple dimensions, of statement and proof is a necessity with untrusted inputs.

Validating a Lean Proof (Lean Reference Manual)

Breaks the trust question down into four incremental checking procedures

lean-lang.org/doc/reference/latest/ValidatingProofs

Validating a Lean Proof: Level I

The "blue double check marks" signify in-process acceptance by the official C++ kernel

```
32  /--  
33  We show that we find arbitrary large (and thus infinitely  
34  many) prime numbers, by picking an arbitrary number `n`  
35  and showing that `n! + 1` has a prime factor larger than `n`.  
36  -/  
✓✓ 37  theorem InfinitudeOfPrimes : ∀ n, ∃ p > n, IsPrime p := by  
38  |   intro n  
39  |   have : 1 < n ! + 1 := by grind [factorial_pos]
```

Protects against "innocent" mistakes:

- incomplete proofs/sorry
- tactics producing incorrect proof terms

... in the current theorem

Validating a Lean Proof: Level II

`#print axioms` lists all axioms (transitively) used by a theorem.

Three built-in axioms relied on pervasively in Lean: choice, propositional extensionality, quotient lifting

The Gold Standard of the pre-AI world.

Protects against

- **inherited** incomplete/incorrect proof terms
- custom axioms

Validating a Lean Proof: Level III

The kernel can be run as its own process: `leanchecker`

Protects against

- incorrect kernel handling by Lean (e.g. imported declarations are trusted)
- metaprograms bypassing the in-process kernel or otherwise corrupting processing

Validating a Lean Proof: Level IV

`comparator` **isolates** statement processing, proof processing, and `leanchecker` into separate, **sandboxed** processes. Optionally runs additional checkers as well.

Protects against

- actively malicious proofs (but not incorrect statements)
- bugs in some but not all checkers

Validating a Lean Proof: Level IV

A **Challenge.lean** file contains only the statement with minimal dependencies for review.

```
theorem FLT_for_comparator (n : ℕ) (hn : 3 ≤ n) (a b c : ℕ) (ha : 0 < a) (hb : 0 < b) (hc : 0 < c) :  
  a ^ n + b ^ n ≠ c ^ n :=  
  sorry
```

Solution.lean then is checked to be a refinement of the challenge with arbitrary further imports.

The solution is accepted if it passes all checkers and axiom checks (i.e. no **sorry**) and its statement plus relevant closure is equal to that in the challenge.

Sourcing Statements

FLT can be stated without additional dependencies. Mathlib provides the statement(!) for any semiring.

[google-deepmind/formal-conjectures](https://github.com/google-deepmind/formal-conjectures) provides the statement of **Navier-Stokes** used by OpenAI.

Buckmaster-Alpöge provide three challenge files importing only Mathlib.

External Checkers

The **Lean Kernel Arena** collects, checks, and profiles external checkers.

At the time of writing, the #1 spot **sokonanoda** (Jeremy Chen, Cambridge) checks Mathlib **17x** as fast as the official kernel.

lean4lean (Mario Carneiro, Chalmers) is a notable port and in-progress formalization of the official kernel and the type theory in Lean itself. Some overlap and cooperation with the **MetaRocq** (INRIA) project.

con-leche (Joachim Breitner, Lean FRO) is a kernel AI-written in Lean with verified consistency, by way of a set-theoretic model. **con-ron** is a verified port to Rust, removing the Lean runtime from the TCB.

comparator, lean4lean, con-leche, and con-ron come **bundled with Lean 4.35+**.

Revisiting the Trusted Code Base at Level IV

- the statement (small and independent, ideally)
 - plus its elaboration
- at least one of the used checkers (impl ~7,000 LoC; verification statement ~100 LoC)
- comparator (~1,000 LoC)
 - plus its compilation and runtime
- the OS sandbox (**bubblewrap**), the OS, the hardware (*many* LoC)

The newest version of comparator allows for producing the proof export file manually, such as in a VM or on a separate machine.

Lean FRO: Shaping the Future of Lean Development

The Lean Focused Research Organization (FRO) is a non-profit dedicated to Lean's development.

Founded in **August 2023**, the organization has 19 members.

Its mission is to enhance critical areas: **scalability**, **usability**, **documentation**, and **proof automation**.

It must reach **self-sustainability by August 2028** and become the **Lean Foundation**.

We are very grateful for all philanthropic support we have received.

Conclusion

The advent of AI proofs has completely changed the trust question for theorem provers.

The default assumption now is that if an agent *could* feasibly find a weakness, it will use it.

Lean is the first major ITP to ship with an isolated checking setup and verified kernel.
